Alerting Abstract: EP A

Genus and/or species specific detection of bacteria in test fluids comprises (1) hybridising bacterial RNA with a primer (I) which is (a) complementary to a genus/species specific region of RNA of certain bacteria, or to a highly conserved region of RNA of bacteria in general, but (b) at its 3'-end is not complementary to RNA of bacteria of other genera or species. (2) elongating the primer in presence of a polymerase and the 4 deoxyribonucleotides, opt with simultaneous or subsequent labelling of the elongation product (EP). (3) denaturing EP and hybridising with a genus/species specific oligonucleotide (II), then (4) detecting hybridisation from the label.

(I) is pref. complementary to RNA of one genus only and (II) will hybridise with RNA of only particular species within that genus. (I) and (II) are derived from r-, m- or t-RNA and can carry different labels.

Polymerisation is pref. with AMV or MMuLV reverse transcriptase, and before hybridisation with (II) EP are sepd. according to size by gel electrophoresis or ascending TLC. The label in EP may be one member of a specific binding pair, with the other partner being bound to a solid phase. Hybridisation with (II) is then done on this phase.

USE/ADVANTAGE - Method can distinguish between RNA differing in only a few bases. (I) and (II) provide two selection stages, so the danger of false assignments is reduced. Method is used e.g. to differentiate between harmful and harmless species
